contributes to its pathogenesis. We investigated the response of endothelial cells (ECs) to exposure to hyperoxic conditions over 14 days. Primary rat pulmonary microvascular ECs (PMVECs) were exposed to normoxia (5% oxygen) or hyperoxia (95%) for 1-14 days. We found that an exposure to 5% oxygen for 14 days resulted in a significant reduction in EC viability and metabolic function. Signaling events in response to VEGF stimulation were not impaired in hyperoxia, but Bax protein expression was upregulated, mitochondrial function was markedly reduced, and cell death occurred in a caspase-

---

dependent manner. Morphological changes included EC thinning, intercellular space widening, and increased permeability. Hyperoxia resulted in extensive mitochondrial and lysosomal damage. Activity of antioxidant enzymes (SOD1/2) was attenuated after 1 day, and they failed to re-establish in cells exposed to hypoxia, a condition accompanied by severe oxidative stress. These observations suggest that oxygen toxicity may occur in vivo by triggering cell death in ECs in an apoptotic manner via the caspase-dependent pathway and inducing oxidative stress in

mitochondria.[Cognitive deficits in Parkinson's disease]. Cognitive impairment is one of the most disabling non-motor symptoms that can occur in Parkinson's disease. It is usually included in the definition of mild cognitive impairment, however its clinical manifestations vary considerably. Although some therapeutic strategies have been developed to ameliorate these impairments, they lack of consistent results. To review the evidence on cognitive and behavioral deficits associated with Parkinson's disease. A systematic review of the literature of last three decades. Cognitive and
